

view by using the wide angle camera
on your phone and having it look
through the tea pot

how it works

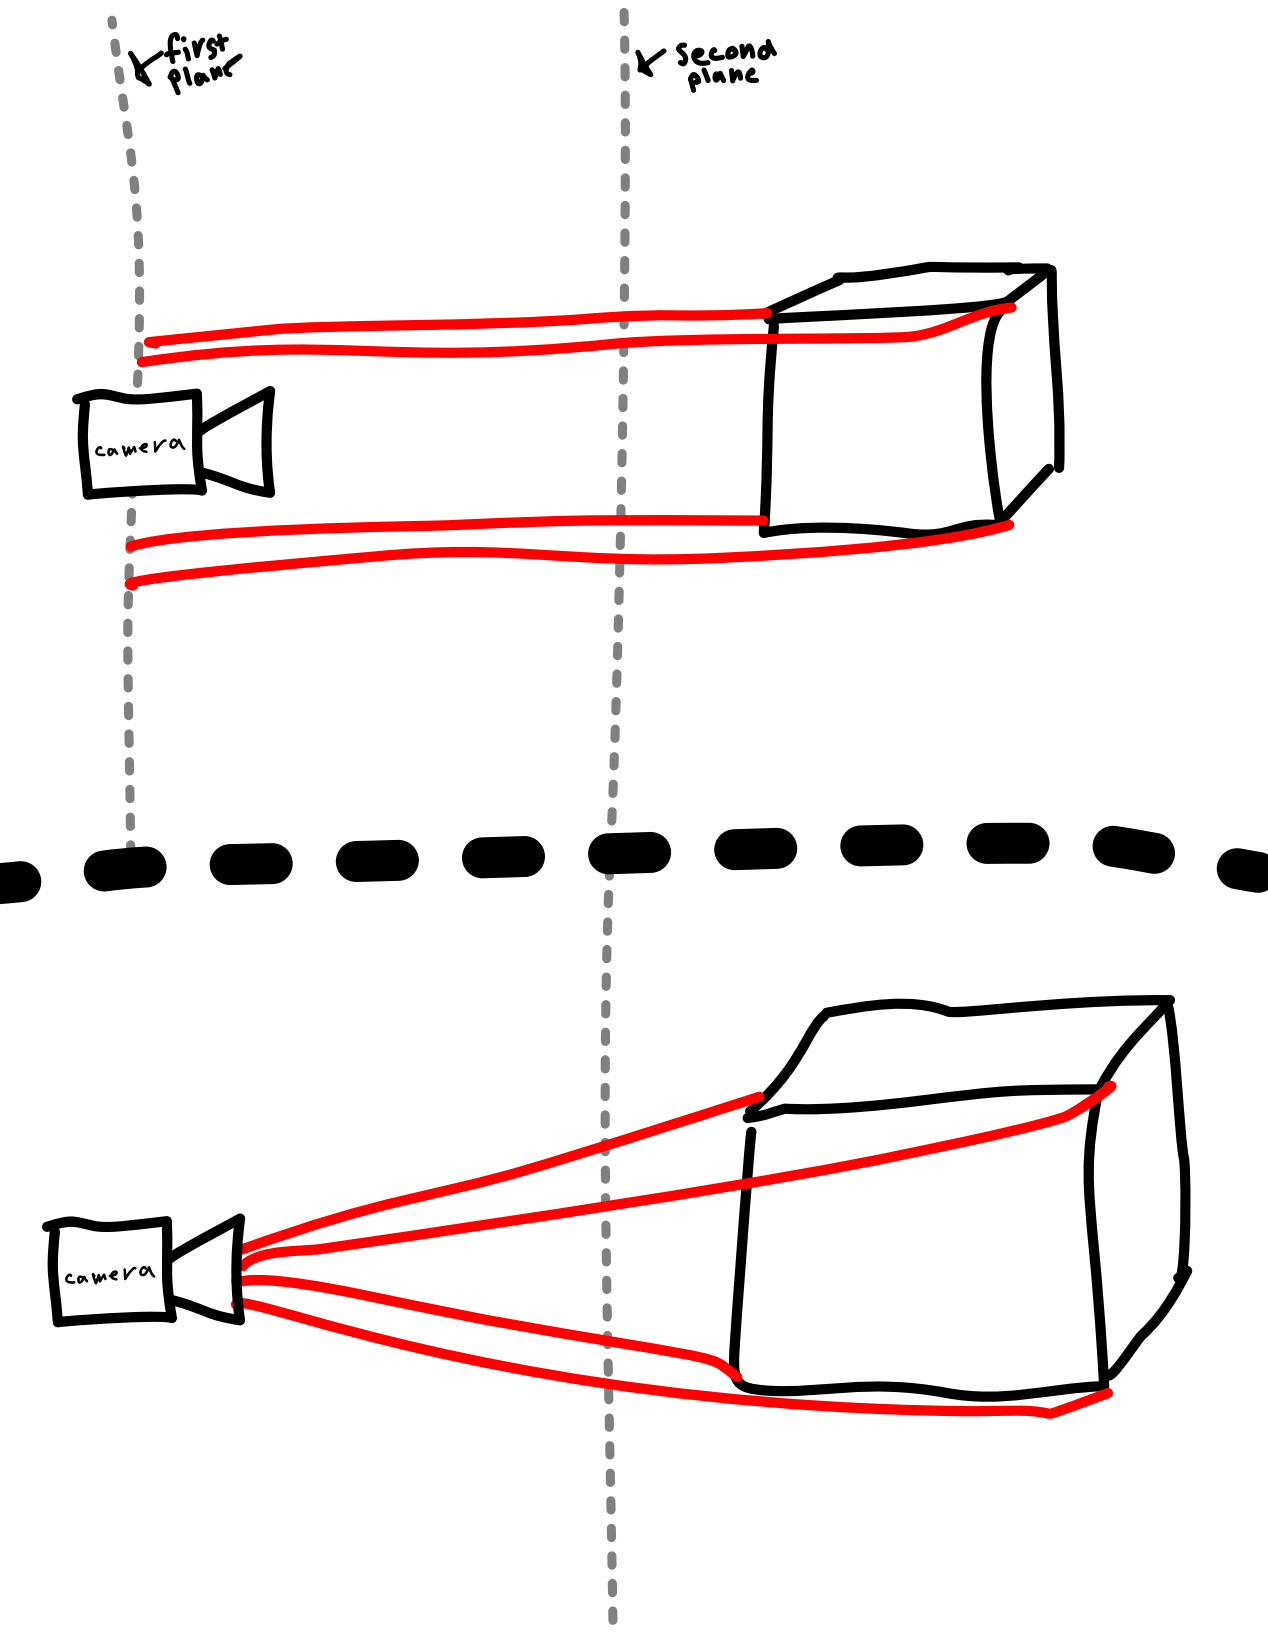

Assume
Straight lines

From the cameras perspective if the vertices of the object are moved along the line made from the camera to the vertices there is no perceptible change in their position (from the cameras pov). From all other angles the object could look dis formed but from the cameras perspective the object is the same.

camera = eye

Assume straight lines

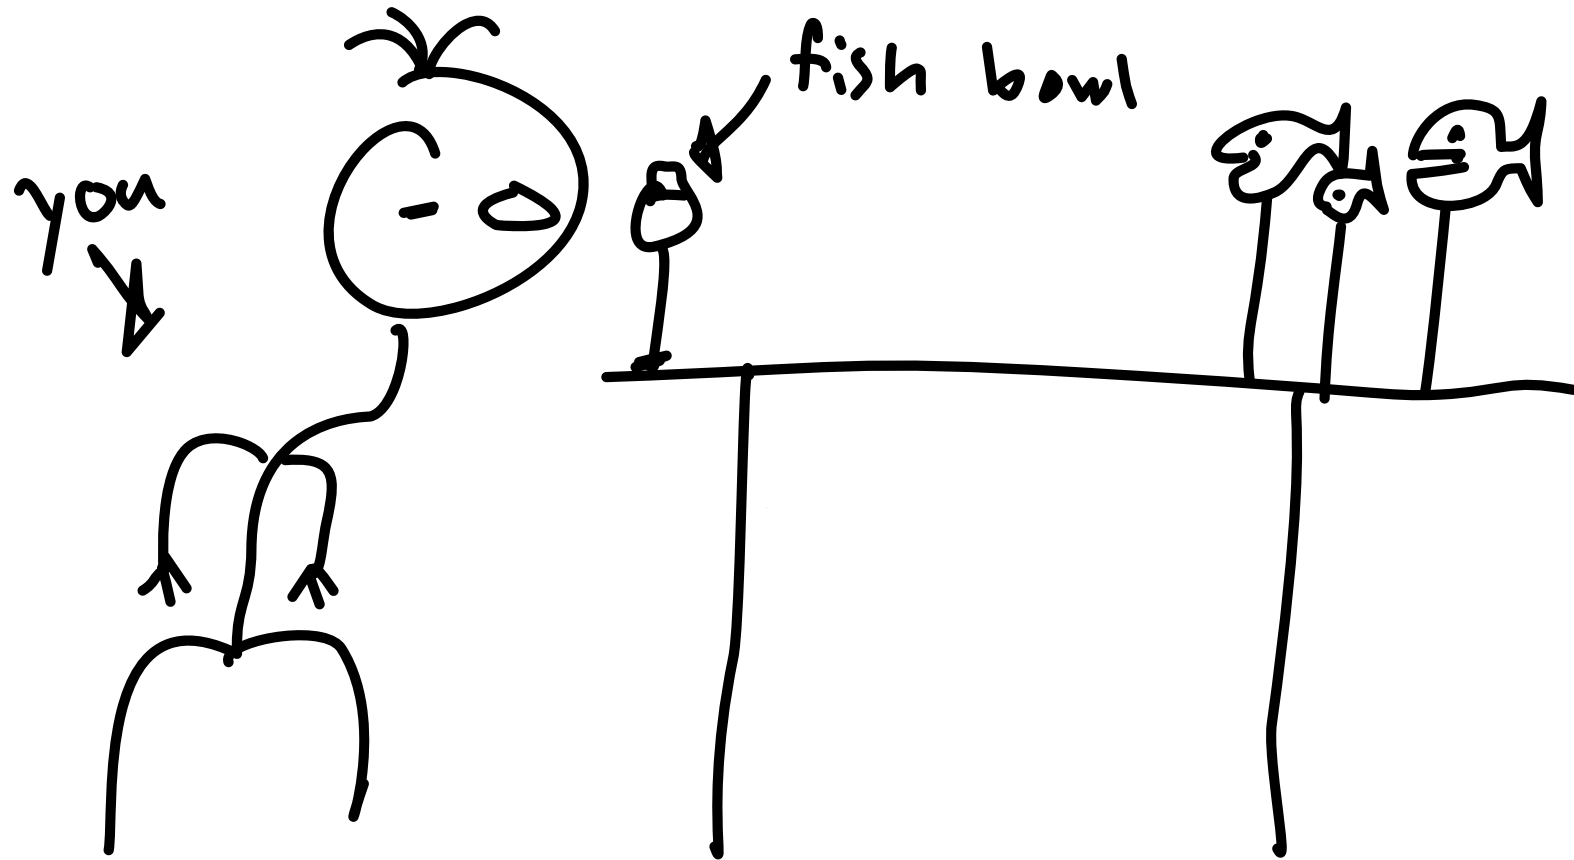

To make an object appear orthographic from a specific point (a camera), you take lines from a plane perpendicular to the camera's direction and shoot rays to the vertices of the object.

Recording the length of the rays and a point where they pass through a second plane, you can then set the origin of the rays to the camera. When the rays go through the same second plane point and the vertices are placed at the length previously measured from the first plane, the object appears in orthographic view from the camera's perspective.

camera = eye
